

Explore Hybrid MPI/OpenMP Scaling on NERSC Systems

Helen He
NERSC User Service

October 28, 2014

Goals and Outline

- **Goals**
 - Not a tutorial on MPI or OpenMP
 - Practical tips and real case studies of hybrid MPI/OpenMP implementations to prepare applications for Cori
- **Outline**
 - Introduction
 - Scaling Tips
 - Process and Thread Affinity
 - Tools for OpenMP
 - Case Studies

Introduction

The Big Picture

- **The next large NERSC production system “Cori” will be Intel Xeon Phi KNL (Knights Landing) architecture:**
 - >60 cores per node, 4 hardware threads per core
 - Total of >240 threads per node
- **Your application is very likely to run on KNL with simple port, but high performance is harder to achieve.**
- **Many applications will not fit into the memory of a KNL node using pure MPI across all HW cores and threads because of the memory overhead for each MPI task.**
- **Hybrid MPI/OpenMP is the recommended programming model, to achieve scaling capability and code portability.**
- **Current NERSC systems (Babbage, Edison, and Hopper) can help prepare your codes.**

Hybrid MPI/OpenMP Reduces Memory Usage

- **Smaller number of MPI processes. Save the memory needed for the executables and process stack copies.**
- **Larger domain for each MPI process, so fewer ghost cells**
 - e.g. Combine 16 10x10 domains to one 40x40. Assume 2 ghost layers.
 - Total grid size: Original: $16 \times 14 \times 14 = 3136$, new: $44 \times 44 = 1936$.
- **Save memory for MPI buffers due to smaller number of MPI tasks.**
- **Fewer messages, larger message sizes, and smaller MPI all-to-all communication sizes improve performance.**

Why Scaling is So Important

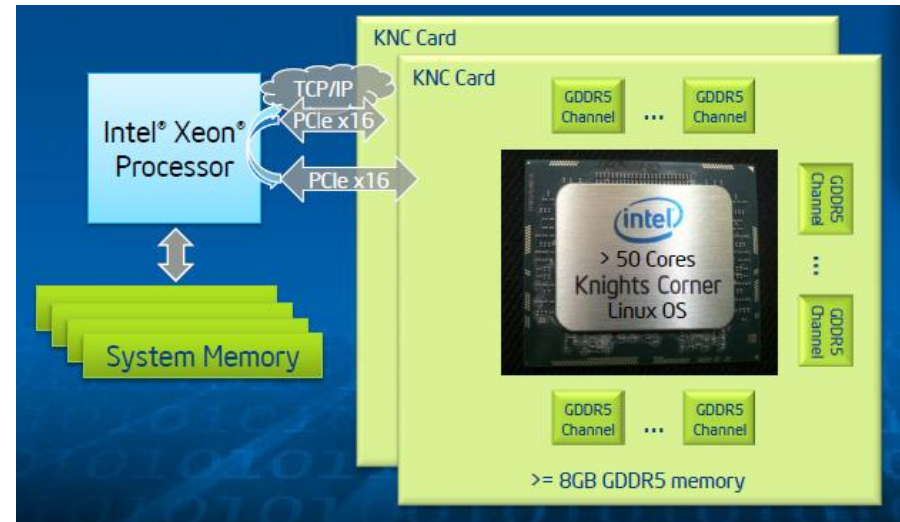

Courtesy of Jim Jeffers and James Reinders

- **Scaling of an application is important** to get the performance potential on the Xeon Phi manycore systems.
- Does not imply to scale with “pure MPI” or “pure OpenMP”
- Does not imply the need to scale all the way to 240-way either
- Rather, should **explore hybrid MPI/OpenMP**, find some sweet spots with combinations, such as: 4 MPI tasks * 15 threads per task, or 8*20, etc.

Babbage

- NERSC Intel Xeon Phi Knights Corner (KNC) testbed.
- 45 compute nodes, each has:
 - Host node: 2 Intel Xeon Sandybridge processors, 8 cores each.
 - 2 MIC cards each has 60 native cores and 4 hardware threads per core.
 - MIC cards attached to host nodes via PCI-express.
 - 8 GB memory on each MIC card
- Recommend to use at least **2 threads per core to hide latency** of in-order execution.

To best prepare codes on Babbage for Cori:

- Use “native” mode on KNC to mimic KNL, which means ignore the host, just run completely on KNC cards.
- Encourage single node exploration on KNC cards with problem sizes that can fit.

Scaling and Tips

Fine Grain and Coarse Grain Models

Program fine_grain

```
!$OMP PARALLEL DO
  do i=1,n
    ... computation
  enddo
!$OMP END PARALLEL DO

... some serial computation ...

!$OMP PARALLEL DO
  do i=1,n
    ... computation
  enddo
!$OMP END PARALLEL DO
end
```

- Program is single threaded except when actively using multiple threads, such as loop processing,
- Pro: Easier to adapt to MPI program.
- Con: thread overhead, serial section becomes bottleneck.

Program coarse_grain

```
!$OMP PARALLEL
!$OMP DO
  do i=1,n
    ... computation
  enddo
!$OMP END DO

!$OMP DO
  do i=1,n
    ... computation
  enddo
!$OMP END DO
!$OMP END PARALLEL
end
```

- Majority of program run within an OMP parallel region.
- Pro: low overhead of thread creation, consistent thread affinity.
- Con: harder to code, prone to race condition.

Memory Affinity: “First Touch” Memory

- Memory affinity: allocate memory as close as possible to the core on which the task that requested the memory is running.
- Memory affinity is not decided by the memory allocation, but by the initialization. Memory will be local to the thread which initializes it. This is called “**first touch**” policy.
- Hard to do “perfect touch” for real applications. Instead, use number of threads few than number of cores per NUMA domain.

Initialization

```
#pragma omp parallel for
for (j=0; j<VectorSize; j++) {
    a[j] = 1.0; b[j] = 2.0; c[j] = 0.0;}
```

Compute

```
#pragma omp parallel for
for (j=0; j<VectorSize; j++) {
    a[j]=b[j]+d*c[j];}
```

Courtesy of Hongzhang Shan

Cache Coherence and False Sharing

- Data from memory are accessed via cache lines.
- Multiple threads hold local copies of the same (global) data in their caches. Cache coherence ensures the local copy to be consistent with the global data.
- Main copy needs to be updated when a thread writes to local copy.
- Writes to same cache line is called false sharing or cache thrashing, since it needs to be done in serial. Use atomic or critical to avoid race condition.
- False sharing hurts parallel performance.

Cache Locality

- **Use data in cache as much as possible**
 - Use a memory stride of 1
 - Fortran: column-major order
 - C: row-major order
 - Access variable elements in the same order as they are stored in memory
 - Interchange loops or index orders if necessary
 - Tips often used in real codes

Why Not Perfect Speedup?

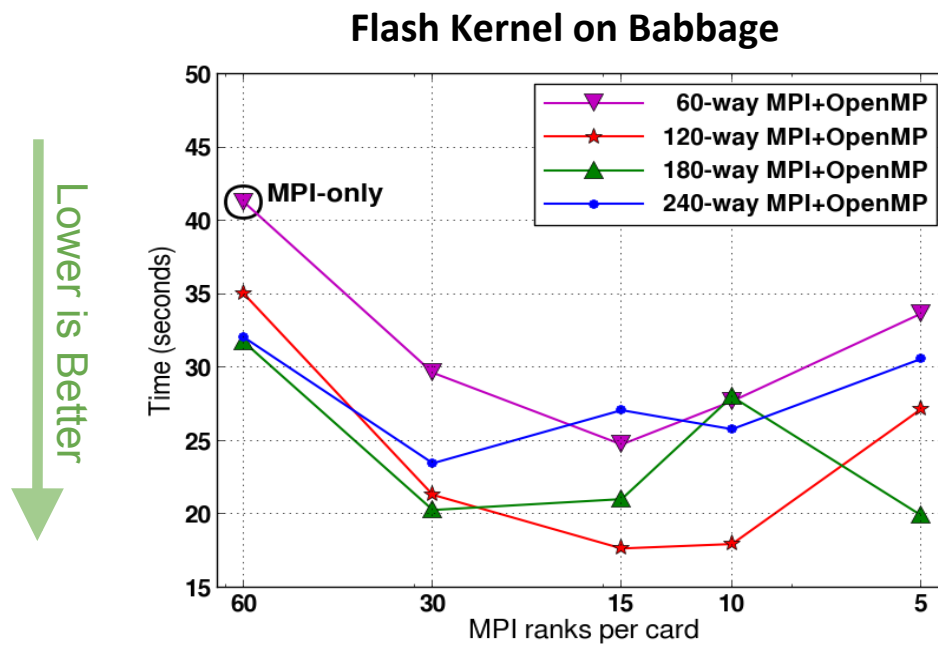

Jacobi OpenMP	Execution Time (sec)	Speedup
1 thread	121	1
2 threads	63	1.92
4 threads	36	3.36

- **Why not perfect speedup?**
 - Serial code sections not parallelized
 - Thread creation and synchronization overhead
 - Memory bandwidth
 - Memory access with cache coherence
 - Load balancing
 - Not enough work for each thread

Programming Tips for Adding OpenMP

- Choose between fine grain or coarse grain parallelism implementation.
- Use profiling tools to find hotspots. **Add OpenMP and check correctness incrementally.**
- Parallelize outer loop and collapse loops if possible.
- Minimize shared variables, minimize barriers.
- Decide whether to overlap MPI communication with thread computation.
 - Simplest and least error-prone way is to use MPI outside parallel region, and allow only master thread to communicate between MPI tasks.
 - Could use MPI inside parallel region with thread-safe MPI.
- **Consider OpenMP TASK.**

MPI vs. OpenMP Scaling Analysis

Courtesy of Chris Daley, NERSC

- Each line represents multiple runs using fixed total number of cores = #MPI tasks x #OpenMP threads/task.
- Scaling may depend on the kernel algorithms and problem sizes.
- In this test case, 15 MPI tasks with 8 OpenMP threads per task is optimal.

- Understand your code by creating the MPI vs. OpenMP scaling plot, **find the sweet spot for hybrid MPI/OpenMP.**
- It can be the base setup for further tuning and optimizing on Xeon Phi.

If a Routine Does Not Scale Well

- Examine code for serial/critical sections, eliminate if possible.
- Reduce number of OpenMP parallel regions to reduce overhead costs.
- Perhaps loop collapse, loop fusion or loop permutation is required to give all threads enough work, and to optimize thread cache locality. Use NOWAIT clause if possible.
- Pay attention to load imbalance. If needed, try dynamic scheduling or implement own load balance scheme.
- Experiment with different combinations of MPI tasks and number of threads per task. Less MPI tasks may not saturate inter-node bandwidth.
- **Test different process and thread affinity options.**
- Leave some cores idle on purpose, for memory capacity or bandwidth capacity.

Process and Thread Affinity for Hopper/Edison

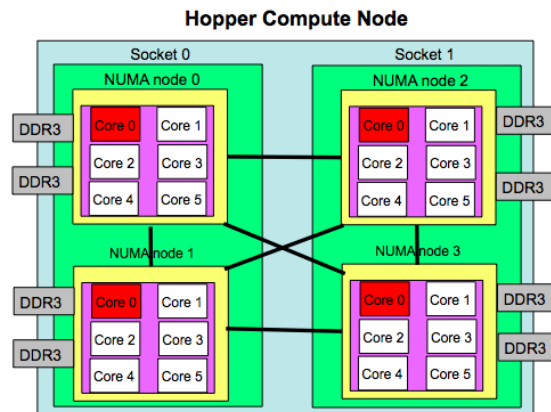

U.S. DEPARTMENT OF
ENERGY

Office of
Science

Hopper/Edison Compute Nodes

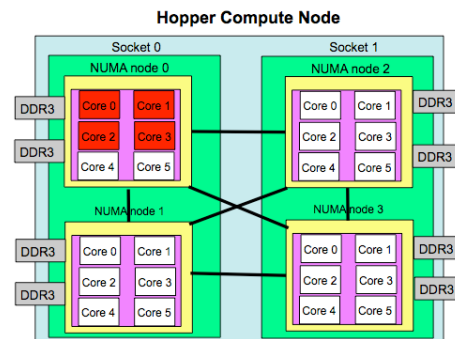

- **Hopper: NERSC Cray XE6, 6,384 nodes, 153,126 cores.**
 - 4 NUMA domains per node, 6 cores per NUMA domain.
- **Edison: NERSC Cray XC30, 5,576 nodes, 133,824 cores.**
 - 2 NUMA domains per node, 12 cores per NUMA domain.
2 hardware threads per core.
- **Memory bandwidth is non-homogeneous among NUMA domains.**

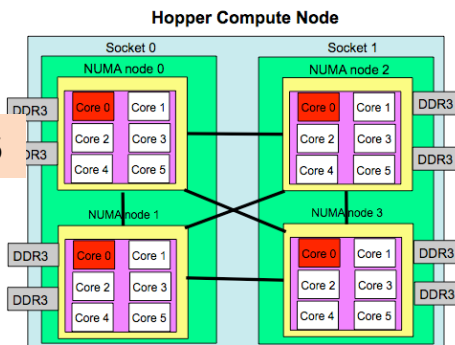

MPI Process Affinity: aprun "-S" Option

- Process affinity: or CPU pinning, binds MPI process to a CPU or a ranges of CPUs on the node.
- Important to spread MPI ranks evenly onto different NUMA nodes.
- Use the "-S" option for Hopper/Edison.

aprun -n 4 -d 6

aprun -n 4 -S 1 -d 6

GTC Hybrid MPI/OpenMP on Hopper, 24,576 cores

Thread Affinity: aprun “-cc” Option

- Thread locality is important since it impacts both memory and intra-node performance.
- Thread affinity: forces each process or thread to run on a specific subset of processors, to take advantage of local process state.
- On Hopper/Edison:
 - The default option is -cc cpu (use for non-Intel compilers)
 - Pay attention to Intel compiler, which uses an extra thread.
 - Use “-cc none” if 1 MPI process per node
 - Use “-cc numa_node” (Hopper) or “-cc depth” (Edison) if multiple MPI processes per node

Process and Thread Affinity for Babbage

Babbage MIC Card

Babbage: NERSC Intel Xeon Phi testbed, 45 nodes.

- 1 NUMA domain per MIC card: 60 physical cores, 240 logical cores.
- Process affinity: spread MPI process onto different physical cores.
- Logical core 0 is on physical core 60.

Thread Affinity: KMP_AFFINITY

- Run Time Environment Variable.
- **none**: no affinity setting. Default setting on the host.
- **compact**: default option on MIC. Bind threads as close to each other as possible

Node	Core 1				Core 2				Core 3			
	HT1	HT2	HT3	HT4	HT1	HT2	HT3	HT4	HT1	HT2	HT3	HT4
Thread	0	1	2	3	4	5						

- **scatter**: bind threads as far apart as possible. Default setting on MIC.

Node	Core 1				Core 2				Core 3			
	HT1	HT2	HT3	HT4	HT1	HT2	HT3	HT4	HT1	HT2	HT3	HT4
Thread	0	3			1	4			2	5		

- **balanced**: only available on MIC. Spread to each core first, then set thread numbers using different HT of same core close to each other.

Node	Core 1				Core 2				Core 3			
	HT1	HT2	HT3	HT4	HT1	HT2	HT3	HT4	HT1	HT2	HT3	HT4
Thread	0	1			2	3			4	5		

- **explicit**: example: `setenv KMP_AFFINITY "explicit, granularity=fine, proclist=[1:236:1]"`
- New env on coprocessors: `KMP_PLACE_THREADS`, for exact thread placement

Thread Affinity: KMP_PLACE_THREADS

- **New setting on MIC only.** In addition to KMP_AFFINITY, can set exact but still generic thread placement.
- **KMP_PLACE_THREADS=<n>Cx<m>T,<o>O**
 - <n> Cores times <m> Threads with <o> of cores Offset
 - e.g. 40Cx3T,1O means using 40 cores, and 3 threads (HT2,3,4) per core
- **OS runs on logical proc 0, which lives on physical core 60**
 - OS procs on core 60: 0,237,238,239.
 - Avoid use proc 0

MPI Process Affinity: I_MPI_PIN_DOMAIN

- **A domain is a group of logical cores**
 - Domains are non-overlapping
 - Number of logical cores per domain is a multiple of 4
 - 1 MPI process per domain
 - OpenMP threads can be pinned inside each domain

- **I_MPI_PIN_DOMAIN=<size>[:<layout>]**

<size> = **omp** adjust to OMP_NUM_THREADS
 auto #CPUs/ #MPI procs

 <n> a number

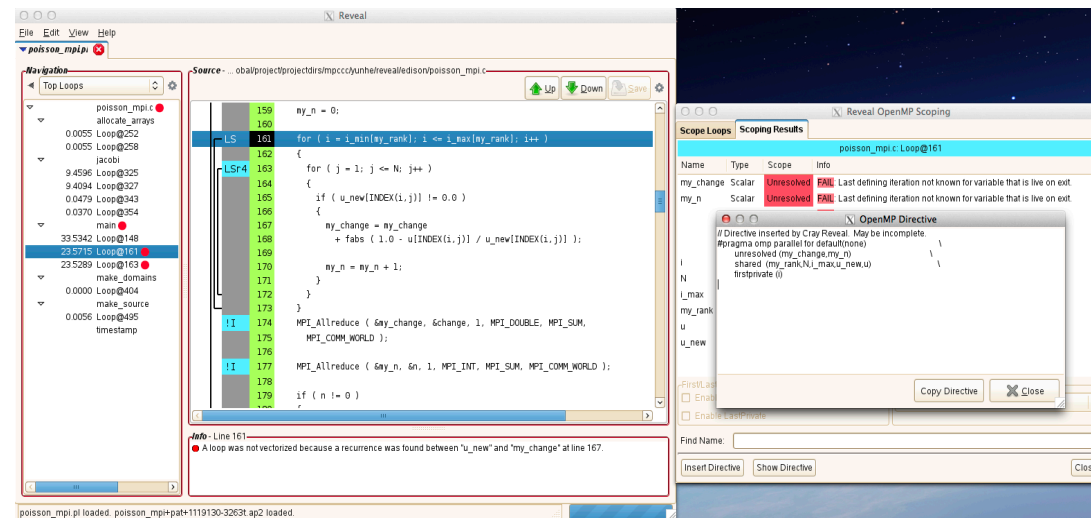

<layout> = **platform** according to BIOS numbering
 compact close to each other
 scatter far away from each other

Tools for OpenMP

Adding OpenMP to Your Program

- On Hopper/Edison, under Cray programming environment, Cray Reveal tool helps to perform scope analysis, and suggests OpenMP compiler directives.
 - Based on CrayPat performance analysis
 - Utilizes Cray compiler optimization information

- On Babbage, Intel Advisor tool helps to guide threading design options.

Performance Analysis And Debugging

- **Performance Analysis**
 - Hopper/Edison:
 - Cray Performance Tools
 - IPM
 - Allinea MAP, perf-reports
 - TAU
 - Babbage:
 - Vtune
 - Intel Trace Analyzer and Collector
 - HPCToolkit
 - Allinea MAP
- **Debugging**
 - Hopper/Edison: DDT, Totalview, LGDB, Valgrind
 - Babbage: Intel Inspector, GDB, DDT

Case Studies

Case Studies Introduction

- **OpenMP parallelizing techniques used in real codes.**
- **LBM on TACC Stampede** (*by Carlos Rosales, TACC*)
 - Add OpenMP incrementally
 - Compare OpenMP affinity
- **MFDn on Hopper** (*by H. Metin Aktulga et al., LBNL*)
 - Overlap communication and computation
- **NWChem on Babbage** (*by Hongzhang Shan et al., LBNL*)
 - CCSD(T)
 - Add OpenMP at the outermost loop level
 - Loop permutation, collapse
 - Reduction, remove loop dependency
 - Fock Matrix Construction (FMC)
 - Add OpenMP to most time consuming functions
 - OpenMP Task
 - Find sweet scaling spot with hybrid MPI/OpenMP

Case Study #1: LBM, Add OpenMP Incrementally

Steps to Parallelize LBM

Compare OpenMP Affinity Choices

- **Lattice Boltzmann Method: a Computational Fluid Dynamics Code.**
- **Actual serial run time for Collision > 2500 sec (*plotted above as 200 sec only for better display*), > 95% of total run time.**
- **Step 1: Add OpenMP to hotspot Collision. 60X Collision speedup.**
- **Step 2: Add OpenMP to the new bottleneck, Stream and others. 89X Stream speedup.**
- **Step 3: Add vectorization. 5X Collision speedup.**
- **Balanced provides best performance overall.**

Case Study #2: MFDn, Overlap Comm and Comp

```
!$OMP PARALLEL
  if (my_thread_rank < 1) then
    call MPI_xxx(...)
  else
    do some computation
  endif
!$OMP END PARALLEL
```

- Need at least **MPI_THREAD_FUNNELED**.
- While master or single thread is making MPI calls, **other threads are computing!**
- Must be able to separate codes that can run before or after halo info is received.
Very hard!
- Lose compiler optimizations.

- MFDn: a nuclear physics code.
- Hopper. Pure MPI: 12,096 MPI tasks.
- Hybrid A: hybrid MPI/OpenMP, 2016 MPI* 6 threads.
- Hybrid B: hybrid A, plus: merge MPI_Reduce and MPI_Scatter into MPI_Reduce_Scatter, and merge MPI_Gather and MPI_Bcast into MPI_Allgatherv.
- Hybrid C: Hybrid B, plus: overlap row-group communications with computation.
- Hybrid D: Hybrid C, plus: overlap (most) column-group communications with computation.

Case Study #3: NWChem CCSD(T), Baseline OpenMP

- Due to memory limitation, can only run with 1 MPI process per MIC.
- OpenMP added at the outermost loops of hotspots: Loop Nests. Scales well up to 120 threads.
- GetBlock is not parallelized with OpenMP. Hyper-threading hurts performance.
- Total time has perfect scaling from 1 to 16 threads. Best time at 120 threads.
- Balanced affinity gives best performance.

Case Study #3: NWChem CCSD(T), More OpenMP Optimizations

- GetBlock optimizations: parallelize sort, loop unrolling.
- Reorder array indices to match loop indices.
- Merge adjacent loop indices to increase number of iterations.
- Align arrays to 64 bytes boundary.
- Exploit OpenMP loop control directive, provide compiler hints.
- Total speedup from base is 2.3x.

Case Study #4: NWChem FMC, Add OpenMP to HotSpots (OpenMP #1)

- Total number of MPI ranks=60; OMP=N means N threads per MPI rank.
- Original code uses a shared global task counter to deal with dynamic load balancing with MPI ranks
- Loop parallelize top 10 routines in TEXAS package (75% of total CPU time) with OpenMP. Has load-imbalance.
- OMP=1 has overhead over pure MPI.
- OMP=2 has overall best performance in many routines.

Case Study #4: NWChem FMC, OpenMP Task Implementation (OpenMP #3)

Fock Matrix Construction — OpenMP Task Implementation

```
c$OMP parallel
myfock() = 0
c$OMP master
current_task_id = 0
mytid = omp_get_thread_num()
My_task = global_task_counter(task_block_size)
for ijk = 2*ntype to 2*ntype+1 step 1 do
  for ij = min(ntype, ijk - 1) to max(1, ijk - ntype) step 1 do
    kl = ijk - ij
    if (my_task .eq. current_task_id) then
      c$OMP task firstprivate(ij,kl) default(shared)
      create_task(ij,kl, ...)
      c$OMP end task
      my_task = global_task_counter(task_block_size)
    end if
    current_task_id = current_task_id + 1
  end for
end for
c$OMP end master
c$OMP taskwait
c$OMP end parallel
Perform Reduction on myfock to Fock matrix
```

- OpenMP task model is flexible and powerful.
- The **task** directive defines an explicit task.
- Threads share work from all tasks in the task pool.
- Master thread creates tasks.
- The **taskwait** directive makes sure all child tasks created for the current task finish.
- Helps to improve load balance.

- Use OpenMP tasks.
- To avoid two threads updating Fock matrix simultaneously, a local copy is used per thread. Reduction at the end.

Case Study #4: NWChem FMC, Run Time

- Flat MPI is limited to a total of 60 ranks due to memory limitation.
- OpenMP #1 uses flat MPI up to 60 MPI processes, then uses 2, 3, and 4 threads per MPI rank.
- OpenMP #2 and #3 are pure OpenMP.
- OpenMP #2 module-level parallelism saturates at 8 threads (critical and reduction related). Then when over 60 threads, hyper-threading helps.
- OpenMP #3 Task implementation continues to scale over 60 cores. 1.33x faster (with 180 threads) than pure MPI.
- The OpenMP Task implementation benefits both MIC and Host.

Case Study #4: NWChem FMC, MPI/OpenMP Scaling and Tuning

- Another way of showing scaling analysis result.
- Sweet spot is either 4 MPI tasks with 60 OpenMP threads per task, or 6 MPI tasks with 40 OpenMP threads per task.
- 1.64x faster than original flat MPI.
- 22% faster than 60 MPI tasks with 4 OpenMP threads per task.

Summary

- **Use Edison/Babbage to help you to prepare for Cori regarding thread scalability (hybrid MPI/OpenMP implementation).**
 - MPI performance across nodes or MIC cards on Babbage is not optimal.
 - Concentrate on optimization on single MIC card.
- **Case studies showed effectiveness of OpenMP**
 - Add OpenMP incrementally. **Conquer one hotspot at a time.**
 - **Experiment with thread affinity choices.** Balanced is optimal for most applications. Low hanging fruit.
 - Pay attention to cache locality and load balancing. Adopt loop collapse, loop permutation, etc.
 - **Find sweet spot with MPI/OpenMP scaling analysis.**
 - Consider OpenMP TASK. Major code rewrite.
 - Consider overlap communication with computation. Very hard to do.
- **Optimizations targeted for one architecture (XE6, XC30, KNC) can help performance for other architectures (Xeon, XC30, KNL).**
